

It is important to note that it is generally considered good practice to avoid modifying global variables within the function, as it can lead to unexpected behaviours and make your code harder to debug.

Example: "Bank Account Simulator"

- Balance is global variable,
- Deposit and Withdraw is modify global
- Other functions are local.

☐ — Balance (Initially = 0),
Deposit, Withdraw

def (deposit):

global Balance change

Deposit, Withdraw.

Print new Balance,
and give a receipt

Use time module to

Print the time of receipt

Local and global variables

A local variable is a variable that is defined within the function and is only accessible within that function. It is created when a function is called and destroyed when a function is destroyed.

On other hand global variable is a variable that is defined outside of a function and is accessible from within any function in your code.

```
x = 10 # Global variable.
def my_function():
    y = 5 # local variable.
    print(y)
```

Now if we want to modify a global variable within a function, this is where the global keyword comes in.

```
x = 10 # global function
def my_function():
    global x
    x = 4
    y = 5
    print(y)
```

```
my_function() # 5
print(x) # 4
# now 10 will change to 4
```
