

when the constructor accept arguments along self.
it is known as parametrized constructor.

These arguments can be used inside the class
to assigned the values of data members.

Ex

Class detail:

```
def __init__(self, animal, group):  
    self.animal = animal  
    self.group = group
```

Obj = Details("Crab", "Crustaceans")

print(Obj.animal, "belong to the", Obj.group)

• Output: Crab belong to the Crustaceans group.

(2)

Default Constructors in Python.

When the constructor does not accept any arguments
from the object and has only one argument
, self, in the constructor, it is known as default
constructor.

Ex

```
def __init__(self):  
    print("hello world")
```

Obj1 = Details()

hello world.

Exercise #23 simple Banking Account class.

Constructor

A constructor is a special method in class use to create and initialize an object in class. There are different types of constructors. Constructor is invoke automatically when an object of class is created.

A constructor is a unique function that get called automatically when an object of class is created. The main purpose of constructor is to initialize or assigned value to the data members of that class. It cannot return any value other than none.

Syntax:

```
def __init__(self):  
    #initialisation.
```

init is one of the reserved function in python. In OOP it is known as constructor.

Types of Constructors

① Parameterized constructor
