Example! Insta account followers/username / bio / followers

Explanation of getter in simple way using insta.

Real world example (Insta profile) with getter

- your followers count is stored in insta server
- you cannot open insta database and read it
- you see followers count in your profile screen

class InstaProfile:

def __init__(self, followers):

self.followers = followers

hidden data

def get_followers(self):

return self.followers

getter

InstaProfile → class

followers → variable

profile screen → getter

opening your profile → calling getter

user = InstaProfile(200)

print(user.get_followers())

profile screen

→ you request instagram

→ Insta show followers

(without getter)

class InstaProfile:

def __init__(self, followers): # suppose if insta account

self.followers = followers private / hidden follower

count

user = InstaProfile(1200)

print(user.followers)

direct access

def get_followers(self):

print("followers are hidden")

return self.followers

Change only getter

- ~~Anyone~~ Anyone can change the followers
- no control
- no realism

Getters
Getters in Python are methods that are used to access the value of an object's property and are typically defined using the @property decorator.

```
class MyClass:  
    def __init__(self, value):  
        self.value = value
```

```
    @property  
    def value(self):  
        return self.value
```

In this example, MyClass has a single property, value which is initialized in the init method. The value method is defined as a getter using the property decorator, and is used to return the value of the value property.

To use the getter, we can create an instance of the MyClass class and then access the value property as if it were attribute.

```
[ obj = MyClass(10) ]  
obj.value  
# 10
```

Safe way to see data, not touching it directly
